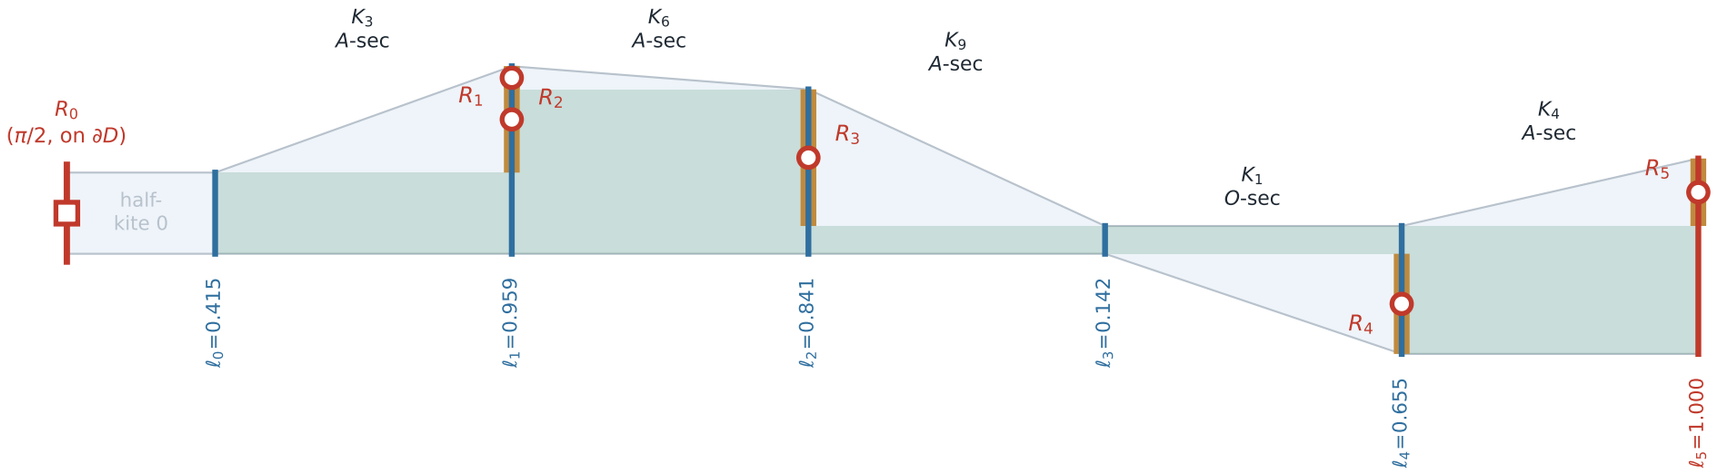
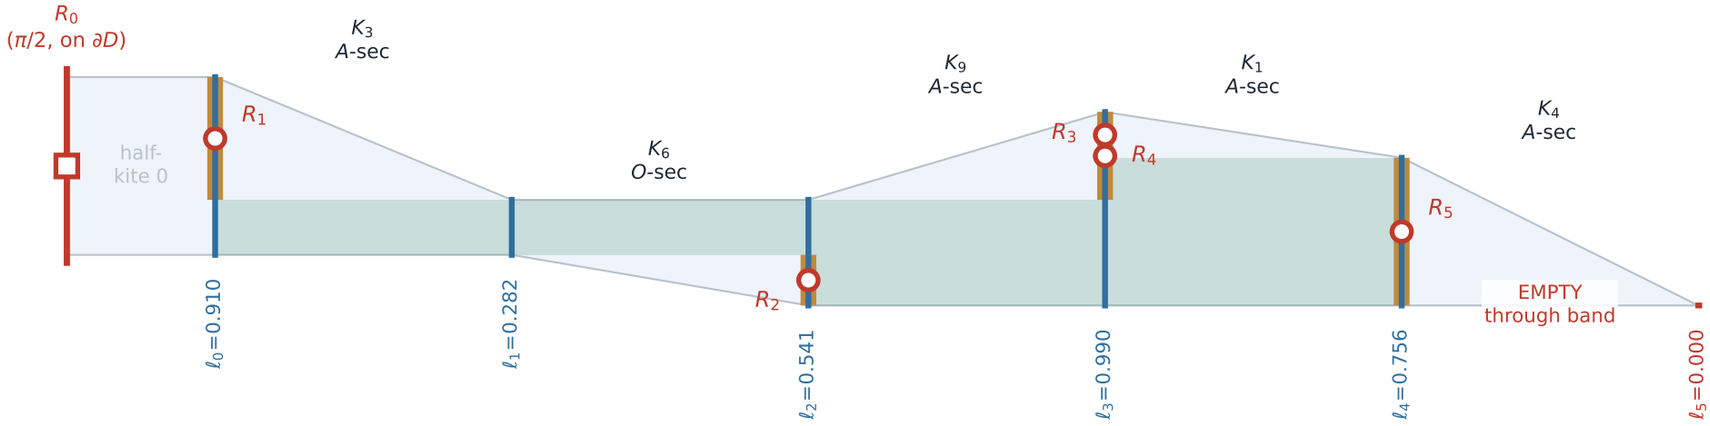
DATA — $D = B/\iota$ (Prop. 2.3): the half-kite 0 followed by m kites, bounded by the two arcs of Fix(ι).
On each kite the fold lives on the FAR (larger) interface and the NEAR one is entirely a through band.

(a) 3/11, $\mathfrak{e} = 0$ — PAIRED. $m = (Q-1)/2 = 5$ interior poles $R_1, \ldots, R_m$.



$\ell_m = 1$ is the strict MAXIMUM: interface $m-1$ is kite m's NEAR edge, so every leaf entering kite m passes through.

(b) 3/11, $\mathfrak{e} = 1$ — LONE. $m = (Q-1)/2 = 5$ interior poles $R_1, \ldots, R_m$.



$\ell_m = 0$ — the fixed interface DEGENERATES. Its two flanking kites have an empty through band, and that is $h = 2$: forced, not imposed.

Horizontal = the chain; vertical = the transverse coordinate of Thm. 4.1. Every kite touches BOTH cone points, so the strip is a drawing convention: the whole lower boundary is Z_O (angle $P\pi/2$ in D), the whole upper boundary is Z_A (angle $(Q-P)\pi/2$).
Green = the through band, gold = the fold, and the pole is the fold's FIXED POINT.
